PROBLEM STATEMENT

Context:

Porter is India's Largest Marketplace for Intra-City Logistics. Leader in the country's \$40 billion intra-city logistics market, Porter strives to improve the lives of 1,50,000+ driver-partners by providing them with consistent earning & independence. Currently, the company has serviced 5+ million customers

Porter works with a wide range of restaurants for delivering their items directly to the people.

Porter has a number of delivery partners available for delivering the food, from various restaurants and wants to get an estimated delivery time that it can provide the customers on the basis of what they are ordering, from where and also the delivery partners.

This dataset has the required data to train a regression model that will do the delivery time estimation, based on all those features

Data Dictionary

Each row in this file corresponds to one unique delivery. Each column corresponds to a feature as explained below.

market id: integer id for the market where the restaurant lies

created_at: the timestamp at which the order was placed

actual_delivery_time: the timestamp when the order was delivered

store primary category: category for the restaurant

order_protocol: integer code value for order protocol(how the order was placed ie: through porter, call to restaurant, pre booked, third part etc)

total_items subtotal: final price of the order

num_distinct_items: the number of distinct items in the order

min_item_price : price of the cheapest item in the order

max_item_price : price of the costliest item in order

total_onshift_partners : number of delivery partners on duty at the time order was placed

total_busy_partners: number of delivery partners attending to other tasks

 $total_outstanding_orders: total\ number\ of\ orders\ to\ be\ fulfilled\ at\ the\ moment$
